

GB 2 294 166 A

FIG. 1

FIG. 1

FIG. 2

1     "Electric Power Switching Arrangements"

2

3     This invention relates to electric power switching  
4     arrangements for controlled switching of AC power from  
5     a supply to a load, and relates more particularly but  
6     not exclusively to electric power switching  
7     arrangements for controlled switching on and/or off of  
8     AC power to a load coupled to the AC power supply  
9     through a transformer which is connected between the  
10    switching arrangement and the load, or which forms part  
11    of the load.

12

13    To control the temperature of an electrically energised  
14    heating load, the AC power input to the load must be  
15    controlled. In its simplest form, control may be  
16    effected by switching the AC supply to the load on and  
17    off in a controlled manner, adjusting the duration of  
18    the "on" time periods relative to the duration of the  
19    "off" time periods. If the load temperature is to  
20    remain broadly constant, the on/off switching frequency  
21    must be fast enough to prevent the load temperature  
22    fluctuating upwards and downwards by excessive amounts  
23    with the "on" and "off" cycling. For an industrial  
24    furnace, a typical power switching frequency might be  
25    of the order of four on/off cycles per minute. The

1 simplest switch means is an electromechanical  
2 contactor, and such switches are widely used in low  
3 cost resistive heating applications. The major  
4 disadvantage with electromechanical contactors is  
5 contact wear, which can result in an unacceptably short  
6 life at the operating frequencies involved (ie several  
7 hundred contactor operations per hour). A further  
8 disadvantage with electromagnetic contactors lies in  
9 the switching action causing electromagnetic  
10 interference due to arcing at the contacts.

11

12 When a contactor is utilised to switch a transformer-  
13 coupled load, the arcing at the contacts is even more  
14 severe than when the contactor is switching a directly  
15 connected resistive load of comparable kVA rating.  
16 Additionally, there is potentially a large inrush  
17 current each time the transformer is switched on.  
18 These technical problems preclude the use of contactors  
19 for switching transformers at the repetition rate  
20 required for temperature-controlled heating loads,  
21 since the repetitive current inrushes would result in  
22 overheating of the transformer, and contact arcing  
23 (especially at switch-off) would unacceptably shorten  
24 contact life.

25

26 It has been proposed to control AC heating loads by  
27 means of thyristors. (A thyristor is a well-known form  
28 of gate-controlled semiconductor switch). Thyristors  
29 have no physical wear mechanisms comparable to those of  
30 an electromagnetic contactor with its moving parts and  
31 current-breaking contacts. In the case of resistive  
32 loads, thyristors can be used to provide zero-voltage  
33 switching on and off, thus almost eliminating the  
34 generation of electromagnetic interference by load  
35 switching operations. However, with a transformer-  
36 coupled load, zero-voltage switching by thyristors is

1 not feasible since it results in a high inrush current.

2

3 It has been proposed to utilise thyristors to control  
4 transformer-coupled loads by operating the thyristors  
5 in "phase-angle" mode, wherein individual half-cycles  
6 of the AC supply are switched on at a controlled phase  
7 angle with respect to the preceding zero-crossing  
8 thereby to chop the supply and thus to control the main  
9 load current. However, use of thyristors as "choppers"  
10 or phase-angle power controllers results in high levels  
11 of electromagnetic interference, harmonic distortion of  
12 the supply current, and a low power factor; for these  
13 reasons phase-angle control is becoming increasingly  
14 unacceptable as a method of control, unless phase-angle  
15 control is necessary to fulfil other process  
16 requirements.

17

18 A proposed variation of phase-angle control of  
19 thyristors is known as "soft-start burst fire" wherein  
20 the supply is switched on and off in bursts of a number  
21 of cycles, with the first few cycles in each "on" burst  
22 being subjected to phase-angle ramping up to minimise  
23 inrush. Soft-start burst fire results in a reduced but  
24 still significant level of interference generation.

25

26 Another technique proposed for controlled switching of  
27 transformer-coupled loads consists of synchronised  
28 switching with delayed firing angle. Assuming no prior  
29 magnetisation of a transformer core, it can be proved  
30 mathematically that the inrush to a single-phase load  
31 will be zero if switch-on occurs at the peak of the  
32 supply voltage waveform. This principle can be  
33 exploited by utilising thyristors. The load must,  
34 however, be switched off in a manner which either  
35 minimises transformer magnetisation or results in  
36 consistent transformer magnetisation, in order that the

1 arrangement can be switched on at an empirically  
2 determined point just prior to the supply voltage  
3 waveform peak at which the inrush will be minimised. A  
4 particular problem of uncontrolled inrushes can arise  
5 with this technique if the transformer is incorrectly  
6 switched off, for example due to a noisy supply, a  
7 supply failure, manual opening of the supply isolator,  
8 etc. Similar unwanted effects can arise if the  
9 installation is modified, or if there is an alteration  
10 of phase sequence or operating frequency.

11

12 Spurious inrushes can result in failure of the special  
13 semiconductor protection fuses, or if a fuse does not  
14 immediately blow in response to a current surge, its  
15 life is likely to be reduced significantly, resulting  
16 in early failure through fatigue (which is aggravated  
17 by rapid on-off switching).

18

19 Thyristor equipment for control of high current loads  
20 (75 Amperes and upwards) is bulky, due to the large  
21 heatsinks required to dissipate the heat losses in the  
22 thyristors. Fans may be required to remove heat from  
23 the sinks, and these considerations can result in an  
24 assembly which is relatively complex and heavy, and  
25 which may be difficult to maintain. As an alternative  
26 to air cooling, water cooling may be employed but this  
27 is also complex.

28

29 In the use of thyristors for switching on loads, it is  
30 not possible to detect and correct for inrushes, since  
31 once the thyristor becomes conductive, the thyristor  
32 cannot be switched off again until the current passing  
33 through the thyristor is reduced to zero which will  
34 only occur at the next zero crossing of the supply  
35 current waveform in supply-commutated systems.

36 Semiconductor devices other than thyristors are

1 available which could possibly be employed for current  
2 limitation. At present the cost and power losses of  
3 such devices generally preclude their use in high  
4 current applications.

5  
6 It is therefore an object of the invention to provide  
7 an electric power switching arrangement for controlled  
8 switching of AC power to a load, which arrangement  
9 obviates or mitigates one or more of the above-  
10 described disadvantages.

11  
12 According to a first aspect of the present invention  
13 there is provided an electric power switching  
14 arrangement for controlled switching of AC power from  
15 an AC power supply to a load, said switching  
16 arrangement comprising input terminal means connectable  
17 to the AC power supply, output terminal means  
18 connectable to the load, first switch means operable to  
19 connect said input terminal means and said output  
20 terminal means, second switch means electronically  
21 operable electrically to connect said input terminal  
22 means to said output terminal means, said first and  
23 second switch means being so connected as to provide  
24 electrically parallel paths for AC power from said  
25 input terminal means to said output terminal means,  
26 said switching arrangement further comprising control  
27 means operable during use of the switching arrangement  
28 to switch on AC power from the supply to the load by  
29 switching said second switch means into an electrically  
30 connective state in a controlled manner which is  
31 supply-synchronised and substantially immediately  
32 thereafter to operate said first switch means into a  
33 connective state, and vice versa upon switch-off.

34  
35 Said second switch means may be switched into an  
36 electrically connective state substantially at a

1 predetermined phase-angle in the voltage waveform of  
2 the AC supply.

3  
4 Said first switch means may be a solid-state switch  
5 means, but said first switch means is preferably a  
6 switch means which is mechanically operable  
7 conductively to connect said input terminal means to  
8 said output terminal means. Said control means is  
9 preferably such that during switch-on, said second  
10 switch means is switched into an electrically non-  
11 conductive state subsequent to operation of said first  
12 switch means into a conductively connective state,  
13 whereby said first switch means thereafter carries the  
14 totality of electric power from the supply to the load,  
15 and vice versa upon switch-off.

16  
17 Said first switch means is preferably a contactor which  
18 may be electromagnetically operable by means of a  
19 solenoid arrangement. The contactor preferably  
20 includes a respective closable contact arrangement in  
21 each pole of the supply, with each said closable  
22 contact arrangement operating substantially  
23 simultaneously.

24  
25 Said second switch means is preferably a semiconductor  
26 switch means which may comprise a respective pair of  
27 anti-parallel-connected thyristors in each pole of the  
28 supply. Alternative forms of semiconductor switch  
29 comprise transistors such as (for example) IGBTs  
30 (insulated gate bipolar transistors), MOSFETs (metal-  
31 oxide/semiconductor field effect transistors), and the  
32 like. Said second switch means may alternatively be an  
33 electronically controllable non-semiconductor switch,  
34 for example a thermionic device such as a thyatron or  
35 a grid-controlled mercury arc rectifier.

36

1 Said second switch means (of whatever form) may be  
2 electrically connected in series with current  
3 interruption means (such as a circuit breaker means or  
4 high breaking capacity fuses) between the input  
5 terminal means and the output terminal means whereby to  
6 provide protection against full currents.

7  
8 According to a second aspect of the present invention  
9 there is provided a combination of an AC power  
10 switching arrangement and a load-coupling means, said  
11 AC power switching arrangement comprising an electric  
12 power switching arrangement according to the first  
13 aspect of the present invention, said load-coupling  
14 means being connected to receive controlled AC power  
15 from the output terminal means of the electric power  
16 switching arrangement, and said load-coupling means  
17 being connectable to deliver controlled AC power to a  
18 load.

19  
20 Said load-coupling means preferably comprises a  
21 transformer.

22  
23 Embodiments of the invention will now be described by  
24 way of example, with reference to the accompanying  
25 drawings, in which:

26  
27 Fig. 1 is a block schematic diagram of a  
28 first embodiment of the invention; and

29  
30 Fig. 2 is a schematic diagram of an  
31 interference suppression circuit which may be  
32 incorporated into the embodiment of Fig. 1.

33  
34 Referring to the drawing, an electric power switching  
35 arrangement 10 is a 3-phase 3-wire AC system having  
36 input terminals 12 and output terminals 14. The

1 Said second switch means (of whatever form) may be  
2 electrically connected in series with current  
3 interruption means (such as a circuit breaker means or  
4 high breaking capacity fuses) between the input  
5 terminal means and the output terminal means whereby to  
6 provide protection against full currents.

7  
8 According to a second aspect of the present invention  
9 there is provided a combination of an AC power  
10 switching arrangement and a load-coupling means, said  
11 AC power switching arrangement comprising an electric  
12 power switching arrangement according to the first  
13 aspect of the present invention, said load-coupling  
14 means being connected to receive controlled AC power  
15 from the output terminal means of the electric power  
16 switching arrangement, and said load-coupling means  
17 being connectable to deliver controlled AC power to a  
18 load.

19  
20 Said load-coupling means preferably comprises a  
21 transformer.

22  
23 Embodiments of the invention will now be described by  
24 way of example, with reference to the accompanying  
25 drawings, in which:

26  
27 Fig. 1 is a block schematic diagram of a  
28 first embodiment of the invention; and

29  
30 Fig. 2 is a schematic diagram of an  
31 interference suppression circuit which may be  
32 incorporated into the embodiment of Fig. 1.

33  
34 Referring to the drawing, an electric power switching  
35 arrangement 10 is a 3-phase 3-wire AC system having  
36 input terminals 12 and output terminals 14. The

1 high breaking capacity gL fuses, connected in series  
2 with the group 20 in the power path paralleling the  
3 power path through the contactor 18. The circuit  
4 breaker or fuses 24 also provide thermal protection for  
5 the cabling associated with the power path through the  
6 thyristor group 20.

7  
8 The power path through the thyristor group 20 may  
9 optionally include further functional entities, for  
10 example a current limiter 26 and/or an interference  
11 suppression circuit 28. The interference suppression  
12 circuit might, for example, comprise a common mode  
13 choke circuit as illustrated in Fig. 2, comprising  
14 three magnetically coupled coils 32 one of which is  
15 connected in each of the three-phase supply lines,  
16 together with first and second capacitors 34 connected  
17 between adjacent three-phase supply lines and a third  
18 capacitor 36 connected between one of the three-phase  
19 supply lines and earth.

20  
21 For reasons to be explained below, the components  
22 included in the thyristor power path, including the  
23 cabling, circuit breaker/fuses 24, the limiter 26 and  
24 the suppressor 28, need not be rated to carry full load  
25 current continuously, beneficially resulting in reduced  
26 size, weight, and cost. Typically, these components  
27 need be rated at about only one fifth of the full load  
28 current.

29  
30 The switching arrangement 10 has a 3-phase 3-wire  
31 transformer load 30 connected to the output terminals  
32 16 to have the AC power thereto controlled in the  
33 manner about to be described. The transformer load 30  
34 generally comprises load elements (for example,  
35 resistive heating elements; not illustrated) coupled to  
36 the terminals 16 through a transformer which carries

1 the entire power from the supply to the load elements.

2

3 The switching arrangement 10 varies the average  
4 consumption of electric power in the load 30 by  
5 switching AC power on and off, typically about 4 times  
6 per minute when equal "on" and "off" times are set (50%  
7 duty cycle). Load power consumption is controlled by  
8 modulating the ratio of "on" time to "off" time. The  
9 control circuit 22 is preferably programmed such that  
10 the modulating algorithm reduces the switching  
11 frequency progressively as the "on" period becomes a  
12 lesser or greater proportion of the duty cycle than the  
13 50% duty cycle previously referred to, and also such  
14 that positive minimum "on" and "off" times are provided  
15 such that switching does not occur too frequently.

16

17 As previously discussed, electric power regulation can  
18 be effected by switching power on and off at a suitable  
19 repetition rate (eg several times per minute), but  
20 there are consequential adverse effects on the power  
21 switch. The present invention avoids or mitigates  
22 these undesirable effects by operating the thyristor  
23 group 20 to shunt the contactor 18 for short periods  
24 overlapping transitions between "closed" and "open"  
25 states of the contactor 18, and moreover avoids or  
26 mitigates the adverse electrical aspects of the load  
27 being a transformer load by suitably timing the gating  
28 of individual thyristors in the group 20, as will now  
29 be detailed.

30

31 In the following description it is assumed that the 3  
32 phases are labelled "R", "Y", and "B", and that the  
33 phase sequence is "R-Y-B".

34

35 As a first step in the "on" switching sequence, the  
36 thyristors in the "R" and "B" phases are switched on

1 simultaneously, at a phase-angle determined empirically  
2 and in the range from 30° to 90° after positive-going  
3 zero crossing of the supply voltage waveform. The  
4 thyristors in the "Y" phase are next switched on 150°  
5 after the "R-B" positive-going zero crossing. The  
6 operating coil in the contactor 18 is then energised to  
7 cause the contactor 18 to commence to close (ie to  
8 switch "on" to its current-carrying conductive state).  
9 After a delay of sufficient duration as to ensure that  
10 the contactor 18 has closed and that contact bounce has  
11 terminated, all thyristors in the group 20 are switched  
12 off simultaneously. Thereby the switching arrangement  
13 10 provides the benefits of controlled phase-angle  
14 switch-on to avoid excessive inrush, but requires the  
15 semiconductor elements involved to carry full-load  
16 current for such a brief period that the thyristors,  
17 and especially their cooling arrangements, circuit  
18 breaker or fuses 24, and cabling can be considerably  
19 de-rated below what is necessary to withstand full-load  
20 current on a continuous basis.

21  
22 The switch-off sequence of the switching arrangement 10  
23 is as follows: With the contactor 18 closed and  
24 conducting AC power from the input terminals 12 to the  
25 output terminals 14, all thyristors in the group 20 are  
26 simultaneously switched on. Next, the operating  
27 solenoid coil of the contactor 18 is de-energised to  
28 cause the contactor 18 to commence to open. After a  
29 delay of sufficient duration as to ensure that the  
30 contactor 18 is fully and continuously open, the  
31 thyristors in the "Y" phase are switched off at the  
32 point of zero current flow on the positive-going edge  
33 of the cycle. The thyristors in the "R" and "B" phases  
34 are then switched off simultaneously at the point of  
35 zero current flow on the next positive-going edge of  
36 their cycle.

1 Variants of these device switching sequences are  
2 possible without departing from the scope of the  
3 invention. For example, during switch-on, the  
4 thyristors for the "B" phase can be switched "on" prior  
5 to those for the "R" phase, provided the thyristors for  
6 the "R" phase are then controlled as previously  
7 detailed for the "R" and "B" phases together. In  
8 general, it is most important that the switching of the  
9 phases should always follow the same sequence, and be  
10 related. It is not satisfactory that (for example) the  
11 "Y" phase thyristors might sometimes switch off after  
12 the switching off of the thyristors for the "R" phase  
13 even if it is switched off at the same point in the  
14 cycle.

15  
16 In a form of the switching arrangement 10 rated to  
17 carry 3-phase loads of up to 300A at 480V, the  
18 thyristors of the group 20 are switched on for a burst  
19 of approximately 140 milliseconds at the beginning and  
20 end of each "on" period. These units accept an input  
21 control signal of 1.5V or 4-20mA, and provide an  
22 integrated unit with all control circuitry, the  
23 thyristors, and an independent output to switch the  
24 contactor coil, with zero voltage switching. The unit  
25 modulates the load power by modulating the ratio of on  
26 to off time of the load, with a nominal switching  
27 frequency of 4 cycles per minute at 50% duty cycle,  
28 corresponding to an input of 3V (50% signal). The  
29 modulating algorithm reduces the switching frequency  
30 progressively as the "on" period becomes a lesser or  
31 greater proportion of the cycle, and provides positive  
32 minimum on and off times, so that the contactor is not  
33 switched on and off too rapidly. The units are  
34 microprocessor based and provide an extensive alarm  
35 strategy, covering the following:-  
36

- 1     1.    Loss of any supply phase.
- 2
- 3     2.    Loss of phase reference (used for synchronising
- 4           the switching action).
- 5
- 6     3.    Loss of power to the contactor coil.
- 7
- 8     4.    Change in phase rotation.
- 9
- 10    5.    Change in operating frequency.
- 11

12     In the case of 1-3, if these events occur while power  
13     is applied to the load, the transformer may be left  
14     incorrectly magnetised, which could result in an inrush  
15     when power is next applied to the transformer.

16

17     4 and 5 would only apply when the unit is first  
18     switched on after alteration of the plant, and again  
19     could result in an inrush when power is next applied to  
20     the transformer.

21

22     Under these circumstances, to prevent the inrush from  
23     tripping the circuit breaker or fuses 24 which protects  
24     the thyristors 20, the contactor 18 is switched on once  
25     without thyristor assistance, the surge being passed  
26     through the contactor. So that these special switch-on  
27     requirements are not lost in the event of power loss, a  
28     non-volatile memory (EEPROM) is used to store the  
29     information prior to shutdown. (With standard  
30     thyristor equipment it is common practice to revert to  
31     a ramped phase-angle start for the first application of  
32     power after the unit has been switched off). There  
33     will inevitably be occasions when a surge is still  
34     passed through the thyristors, but with this apparatus  
35     an alarm will sound, and all that should be required is  
36     to reset the circuit breaker or replace the fuses 24,

1 rather than the expensive and time-consuming task of  
2 replacing semiconductor fuses.

3  
4 In the case of 1, loss of a supply phase indicating the  
5 operation or failure of the circuit breaker or fuses  
6 24, the apparatus may be adapted to switch to a  
7 "contactor-only" mode of operation, so that power  
8 continues to be supplied to the load 30 without the use  
9 of the switching arrangement 10. This is acceptable  
10 for limited time periods and allows an on-going job to  
11 be completed prior to remedial action being taken to  
12 restore the lost phase. An alarm draws attention to  
13 the fault, without shutting down the power supply  
14 altogether.

15  
16 Advantages of the preferred embodiment of the invention  
17 are as follows:-

18  
19 The invention is a solid state device, intended for use  
20 in conjunction with an electromechanical contactor, for  
21 switching transformer loads in the synchronous mode  
22 with delayed start angle. The contactor carries the  
23 main load current, but the thyristors are switched on  
24 briefly at the start and end of the "on" period, to  
25 provide switching which is synchronised to the supply  
26 frequency. This system provides significant benefits:-

- 27  
28 1. The thyristors are smaller for a given load  
29 current, and the heat dissipation is very  
30 considerably reduced, resulting in a compact  
31 lightweight device of simple mechanical  
32 construction, which is readily replaced or  
33 repaired in the event of failure.  
34  
35 2. The contactor life is very much extended, because  
36 the contacts are not carrying the main load

1 current at the time of switching. This almost  
2 completely eliminates arcing.

3  
4 3. The thyristors may be protected against the  
5 expected levels of fault current (limited by the  
6 transformer impedance) using a standard miniature  
7 or moulded case circuit breaker or HBC gL fuses.  
8 The circuit breaker or fuses also provide thermal  
9 protection for the reduced sized cabling  
10 associated with the thyristor device (typically  
11 1/5 the full load current).

12  
13 4. Levels of electromagnetic interference are low, as  
14 arcing in the contactor is suppressed by the  
15 thyristors.

16  
17 5. The use of a contactor in association with the  
18 thyristor enables independent fail-safe action in  
19 the event of the short circuit of a thyristor,  
20 which might otherwise result in furnace  
21 overheating; an independent over-temperature  
22 sensor and control instrument may also be  
23 required.

24  
25 The concept may be extended in the following ways:-

26  
27 1. Further circuit elements to reduce electromagnetic  
28 interference may be incorporated in the low  
29 current thyristor path, where these devices would  
30 not require to be rated to carry the full load  
31 current. This could have a very significant size,  
32 weight and cost benefit. The circuit of Fig. 2 is  
33 one preferred example.

34  
35 2. Devices other than thyristors could be used in  
36 conjunction with detection circuitry to limit

inrush or surge currents automatically. In this case the greater heat loss and expense of these devices would be offset by the smaller size of devices required due to the short conduction period. The use of insulated gate bipolar transistors (IGBT's) is a particularly preferred alternative to thyristors.

3. The concept is potentially applicable to other load types, when the switching characteristics would be modified to suit the load requirements.
4. The preferred form of device constituting the first switch means is preferably an electromechanically operated contactor, but other forms of mechanically operated switch may be employed such as (for example) pneumatically operated switches and hydraulically operated switches.
5. While the preferred form of the first switch means is a contactor, it is within the scope of the invention that the first switch means be some other type of switch means such as (for example) a solid state switch means, with the power path through said second switch means being used primarily to fit interference suppression devices of a lower current rating than is necessary on a basis of a continuous rating.
6. While the preferred operation of the second switch means is for the second switch means to be switched into an electrically connective state substantially at a predetermined phase angle in the voltage waveform of the AC supply, it is possible within the scope of the invention to

1       substitute other forms of controlled switching  
2       which are synchronised to the supply. This could  
3       (for example) allow the possibility of sensing  
4       inrushes and of controlling the point of switch-on  
5       accordingly. If employing IGBTs as the second  
6       switch means (thereby to be independent of current  
7       zeroes for device switch-off), it would be  
8       possible to chop the AC supply at a relatively  
9       high frequency (ie to switch the IGBTs on and off  
10      several or many times within each cycle of the  
11      supply), and by altering the mark/space ratio of  
12      this high frequency chopping, effectively limit  
13      the current taken by the load. The use of such  
14      devices is facilitated because the higher heat  
15      losses are mitigated by the short duration of the  
16      conduction periods. It might also be desired to  
17      use ramped phase-angle control, making use of the  
18      low current characteristic (in the longer term) of  
19      the AC power path through the second switch means  
20      to reduce the size of the associated suppression  
21      circuits.

22  
23      Other modifications and variations can be adopted  
24      without departing from the scope of the invention.

1     **Claims**

2

3     1.     An electric power switching arrangement for  
4     controlled switching of AC power from an AC power  
5     supply to a load, said switching arrangement comprising  
6     input terminal means connectable to the AC power  
7     supply, output terminal means connectable to the load,  
8     first switch means operable to connect said input  
9     terminal means and said output terminal means, second  
10    switch means electrically operable electrically to  
11    connect said input terminal means to said output  
12    terminal means, said first and second switch means  
13    being so connected as to provide electrically parallel  
14    paths for AC power from said input terminal means to  
15    said output terminal means, said switching arrangement  
16    further comprising control means operable during use of  
17    the switching arrangement to switch on AC power from  
18    the supply to the load by switching said second switch  
19    means into an electrically connective state in a  
20    controlled manner which is supply-synchronised and  
21    substantially immediately thereafter to operate said  
22    first switch means into a connective state, and vice  
23    versa upon switch-off.

24

25    2.     An arrangement as claimed in Claim 1, wherein said  
26    second switch means may be switched into an  
27    electrically connective state substantially at a  
28    predetermined phase-angle in the voltage waveform of  
29    the AC supply.

30

31    3.     An arrangement as claimed in Claim 2, wherein said  
32    second switch means comprises a semiconductor switch  
33    means.

34

35    4.     An arrangement as claimed in Claim 3, wherein said  
36    semiconductor switch means comprises a respective pair

1 of anti-parallel-connected thyristors in each pole of  
2 the supply.

3  
4 5. An arrangement as claimed in Claim 3, wherein said  
5 semiconductor switch means comprises transistors.

6  
7 6. An arrangement as claimed in Claim 5, wherein said  
8 transistors comprise insulated gate bipolar transistors  
9 or metal-oxide/semiconductor field effect transistors.

10  
11 7. An arrangement as claimed in Claim 2, wherein said  
12 second switch means comprises an electronically  
13 controllable non-semiconductor switch.

14  
15 8. An arrangement as claimed in Claim 7, wherein said  
16 electronically controllable non-semiconductor switch  
17 comprises a thermionic device such as a thyatron or a  
18 grid-controlled mercury arc rectifier.

19  
20 9. An arrangement as claimed in any preceding Claim,  
21 wherein said second switch means is be electrically  
22 connected in series with current interruption means  
23 between the input terminal means and the output  
24 terminal means whereby to provide protection against  
25 full currents.

26  
27 10. An arrangement as claimed in Claim 9, wherein said  
28 current interruption means comprises circuit breaker  
29 means or high breaking capacity fuses.

30  
31 11. An arrangement as claimed in any preceding Claim,  
32 wherein said first switch means comprises a solid-state  
33 switch means.

34  
35 12. An arrangement as claimed in any one of Claims 1  
36 to 10, wherein said first switch means comprises a

1 switch means which is mechanically operable  
2 conductively to connect said input terminal means to  
3 said output terminal means.  
4

5 13. An arrangement as claimed in Claim 12, wherein  
6 said first switch means comprises a contactor which is  
7 electromagnetically operable by means of a solenoid  
8 arrangement.  
9

10 14. An arrangement as claimed in Claim 13, wherein  
11 said contactor includes a respective closable contact  
12 arrangement in each pole of the supply, with each said  
13 closable contact arrangement operating substantially  
14 simultaneously.  
15

16 15. An arrangement as claimed in any preceding Claim,  
17 wherein said control means is such that during switch-  
18 on, said second switch means is switched into an  
19 electrically non-conductive state subsequent to  
20 operation of said first switch means into a  
21 conductively connective state, whereby said first  
22 switch means thereafter carries the totality of  
23 electric power from the supply to the load, and vice  
24 versa upon switch-off.  
25

26 16. An arrangement as claimed in any preceding Claim,  
27 wherein said second switch means is electrically  
28 connected in series with current limiting means.  
29

30 18. An arrangement as claimed in any preceding Claim,  
31 wherein said second switch means is electrically  
32 connected in series with interference suppression  
33 means.  
34

35 19. An arrangement as claimed in Claim 18, wherein  
36 said interference suppression means includes a common

1 mode choke circuit.

2

3 20. An arrangement as claimed in any preceding Claim,  
4 wherein said control means is adapted to activate an  
5 alarm and to switch said second switch off in response  
6 to loss of current in any one phase of said second  
7 switch means.

8

9 21. A combination of an AC power switching arrangement  
10 and a load-coupling means, said AC power switching  
11 arrangement comprising an electric power switching  
12 arrangement as claimed in any preceding Claim, said  
13 load-coupling means being connected to receive  
14 controlled AC power from the output terminal means of  
15 the electric power switching arrangement, and said  
16 load-coupling means being connectable to deliver  
17 controlled AC power to a load.

18

19 22. A combination of an AC power switching arrangement  
20 and a load-coupling means as claimed in Claim 21,  
21 wherein said load-coupling means preferably comprises a  
22 transformer.

23

24 23. An electric power switching arrangement  
25 substantially as hereinbefore described with reference  
26 to the accompanying drawings.

27

28 24. A combination of an AC power switching arrangement  
29 and a load-coupling means substantially as hereinbefore  
30 described with reference to the accompanying drawings.
